1 Simply-Typed λ -Calculus

1.1 Typing Derivations

1.2 Programming with Extensions

1. Define the subtraction function sub in the simply-typed λ -calculus extended with Peano numbers (**0** and **succ**) and fixed point operator fix.

```
\begin{aligned} & \text{fix } (\lambda \ fsub : \mathbf{Nat} \to \mathbf{Nat} \to \mathbf{Nat} \ . \\ & \lambda \ m : \mathbf{Nat} \ . \ \lambda \ n : \mathbf{Nat} \\ & & \text{if } (\mathbf{iszero} \ m) \\ & & \text{then } \mathbf{0} \\ & & \text{else } (\mathbf{succ} \ (fsub \ (\mathbf{pred} \ m) \ n)) \ ) \end{aligned}
```

2 System- \mathcal{F}

2.1 Parametric Polymorphism

- 1. Define the polymorphic function I.
- 2. Define the polymorphic function K.
- 3. Define the polymorphic function S.
- 4. Define I in terms of S and K.

2.2 Typing Church-Encodings

- 1. Church-numerals
- 2. Church-booleans
- 3. Church-pairs
